1

Production trajectory — **229 runs**

over 217 ligands, 6 of them simulated in triplicate, with a frame written every 10 ps

2

Periodic boundary — **4 corrections**

each molecule made whole along its own bonds, kept from jumping between frames and held in the first-frame image, and only then the receptor superposed by Kabsch

3

Analysis window — **20 ns**

the first 5 ns of every run discarded and the same 20 ns analysed for every ligand

4

Descriptors — **32 of them**

persistences, fluctuations and event counts, 14 of them one per gorge-lining residue, and none of them a pose descriptor averaged over frames

5

Reliability filter — **11 of 32**

a descriptor qualifies where the spread between ligands is at least twice the spread between replicates of the same ligand

Two feature sets, both scored

the 11 that pass the filter, with the heavy-atom count, give 12 features
all 32, with the same covariate, give 33
one row per ligand over 217 of them, and a signed difference per pair over 145 development pairs
